The first part of the paper is devoted to a discussion of the  
 various methods which have been proposed for the determination of  
 the rate of reaction between a radical and a molecule. The most  
 common of these is the method of initial rates, in which the  
 initial concentration of the radical is varied and the initial  
 rate of reaction is measured. This method is simple and direct,  
 but it is subject to a number of errors, particularly those  
 arising from the determination of the initial concentration of  
 the radical. A more accurate method is the method of  
 continuous variation, in which the concentration of the radical  
 is varied and the rate of reaction is measured at a constant  
 concentration of the molecule. This method is more complicated,  
 but it is more accurate than the method of initial rates.  
 The second part of the paper is devoted to a discussion of the  
 various factors which influence the rate of reaction between a  
 radical and a molecule. These factors include the nature of the  
 radical, the nature of the molecule, the temperature, and the  
 concentration of the reactants. The rate of reaction is  
 generally found to increase with increasing temperature and  
 increasing concentration of the reactants. The nature of the  
 radical and the nature of the molecule also influence the rate  
 of reaction, but the effect is more complicated and is not  
 discussed in detail in this paper.
